

Climate Crisis Accelerates Biodiversity Collapse and Pollution

✦ This title was summarized by AI from the post below.

Marta Segura

The crisis we face extends far beyond what any single diagram can capture.

Human-caused climate change is accelerating forest loss, biodiversity collapse, and the degradation of carbon sinks that still protect us today. It's increasing pandemic risks. Our extractive economy—built on plastics, fast fashion, and disposable products—has turned us into a self-consuming system, like a snake eating its own tail.

A transition to a circular economy could benefit everyone, not just a privileged few. Yet too many leaders remain focused on short-term electoral gains rather than the long-term survival of our planet and its inhabitants.

I refuse to accept a future of escalating homelessness—for people or animals—anywhere in the world.

Humans and animals are meant to coexist and thrive together. The path forward requires us to:

Embrace regenerative practices over extractive ones

Prioritize planetary health alongside economic metrics

Demand leadership that thinks beyond election cycles

The question isn't whether we can afford to change. It's whether we can afford not to.

A new OECD Outlook shows that under current policies, by 2050, we face:

- Global temperatures rising to 2.1°C
- Continued biodiversity collapse
- Plastic waste up 66%
- Fossil fuel use is still increasing
- Agriculture is driving 87% of land conversion

The triple planetary crisis is accelerating — and we're still treating [#climatechange](#), [#biodiversity](#) loss and [#pollution](#) as separate problems. They are not.

A new [OECD - OCDE](#) Outlook shows that under current policies, by 2050 we face:

- Global temperatures rising to 2.1°C
- Continued biodiversity collapse
- Plastic waste up 66%
- Fossil fuel use still increasing

 Agriculture driving 87% of land conversion

Environmental pressures are growing faster than our ability to manage them because the root causes are shared, and our policies remain siloed.

Integrated solutions exist. And they work best when grounded in science and data.

This is exactly where the [World Meteorological Organization](#)'s role is critical:

- ✓ Providing authoritative climate and Earth system data
- ✓ Strengthening early warning systems
- ✓ Supporting countries to integrate climate information into energy, land use, pollution control and national planning
- ✓ Helping align policies with the real behaviour of the atmosphere, oceans and ecosystems

We cannot solve a connected crisis with disconnected policies.
